

A quick word on the `remove()` method

Traditional approach

We've seen that the DOM provides us with a few methods we can access to remove elements. We've looked at `removeChild()` for example.

But, there's a better way of removing an element from the DOM than calling `parent.removeChild(element)` on its parent.

Wait for it

New approach

We can use the `remove()` method, like so: `element.remove()`. In time, this will probably become the standard and idiomatic way of removing an element from the DOM.

The `.remove()` method was added to the DOM Living Standard in 2011, and has since been implemented by Chrome, Safari, Firefox, Opera, and Edge. And in case you were wondering, NO, it has never been supported in any version of Internet Explorer.

Hope you're having fun and enjoying the course.

See you in the next lecture.
